Terminology

This section defines all the terms used in the funktion project

Function

A function is some source code to implement a function in some programming language like JavaScript, python or ruby.

Runtime

A runtime represents the kubernetes Deployment metadata required to take a function source in some programming language and implement it as one or more pods.

The funktion operator then detects a new function resource being created or updated and creates the associated runtime deployment

Connector

A connector represents a way to connect to some event source, including most network protocols, transports, databases, messaging systems, social networks, cloud services and SaaS offerings. Funktion supports over 200 event sources.

At the implementation level a Connector represents the kubernetes Deployment metadata required to take the Flow and implement it as one or more kubernetes pods.

Flow

A flow is a sequence of steps such as consuming events from an endpoint or invoking a function.

For example here is a sample flow in YAML format.

```
flows:
- steps:
- kind: endpoint
    uri: timer://foo?fixedRate=true&period=5000
    - kind: endpoint
    uri: http://myendpoint/
```

Note that a Flow resource can contain multiple sequential flows. Each flow object in the YAML is a sequence of steps.

Creating a flow results in the funktion operator creating an associated Deployment which implements the flows.

Funktion Operator

The funktion operator is a runnning pod in kubernetes which monitors for all the funktion resources like function, runtime, connector and flow and creates, updates or deletes the associated kubernetes deployments and services so that as you create a flow or function the associated kubernetes resources are created.
